
Sticky snapping out Brownian motion is a Feller process on κ copies of $[0, \infty]$ (here $\kappa = 3$), which on the ith copy behaves like a one-dimensional sticky Brownian motion with stickiness coefficient a_i/b_i. After spending enough time at $(0, i)$ the process jumps to one of the points $(0, j)$, $j \neq i$, to continue its motion on the corresponding copy of $[0, \infty]$, and so on. Times between jumps are governed by parameters c_i.
